Attn: Gene Taylor

Dear Gene:

It is my pleasure to submit to you the Final Technical Memorandum on the "Update of the HBA Hydrologic Investigation in the Arroyo Seco Cone Area".

The memorandum documents the work on estimation of the Reliz Creek watershed surface flow contributions, estimation of the maximum recharge rate and thus a revised estimate of the hydraulic conductivity of the streambed material for the Arroyo Seco, and re-evaluation of the hydrologic benefits of the operations of the reservoirs during the historical period. The memorandum, also presents a section on the scope and accuracy of the application of the Salinas Valley Integrated Ground and Surface water Model (SVIGSM) for various studies in the Valley.

The report concludes that the hydrologic benefit received in the Arroyo Seco Cone area as a result of the historical operations of the Nacimiento and San Antonio reservoirs is approximately 0.4 feet less than the previous estimate (April 1998). The report also concludes that the current updates made to the SVIGSM have not resulted in significant changes in hydrologic benefits in other areas of the Valley compared to the April 1998 HBA report.

It has certainly been a pleasure working with you and your staff on this exciting project, and I look forward to be of further assistance to the Agency.

Please do not hesitate to contact me, if you have any questions.

Sincerely Yours,

A handwritten signature in black ink, appearing to read "S. Ali Taghavi".

The purpose of this Technical Memorandum is to document the work performed for an update of the Historical Benefits Analysis (HBA) based upon additional hydrologic investigations in the Arroyo Seco Cone area.

Introduction

The Monterey County Water Resources Agency (MCWRA) conducted a unique planning study to determine the benefits of operation of Nacimiento and San Antonio reservoirs during the historical period 1949 to 1994. This study, named the Historical Benefits Analysis (HBA) attempted to estimate the historical benefits of the operation of the reservoirs from hydrologic (water supply), flood control, and economic viewpoints. The hydrologic benefits were estimated, primarily, based on average annual changes in ground water levels during the historical period of operation of reservoirs. The impact of these changes on water supply facilities, such as production wells was also evaluated.

The hydrologic benefits were evaluated using the Salinas Valley Integrated Ground and Surface water Model (SVIGSM). To prepare the SVIGSM for the HBA study, the hydrologic database, and land and water use data were extended back to 1949, followed by a model re-calibration for the 1949-94 period. The HBA study was conducted in 1997-98, and the final report was published in April 1998.

After the completion of the HBA final report, questions were raised by property owners in the Arroyo Seco Cone area regarding the accuracy of recharge to the ground water basin in the Cone area contributed by Salinas River flows. This coalition of property owners was of the opinion that the Arroyo Seco was the primary source of recharge to the Cone, and the recharge from Salinas River has little or no effect on the ground water basin in the Cone area. Since the April 1998 HBA study concluded that there are up to 5.9 feet of average annual benefits as higher ground water levels in the Arroyo Seco Cone area, as a result of the operation of Nacimiento and San Antonio reservoirs, the Coalition requested a re-evaluation of the distribution of benefits in the Cone based on new hydrogeologic information received after the April 1998 study was completed.

In subsequent meetings between the Agency staff and technical representatives hired by the property owners, it was decided that additional data outside the SVIGSM modeling period could be used to refine estimates of the Arroyo Seco maximum recharge rate and streambed hydraulic conductivity. Further, it was agreed that an estimate of flow from Reliz Creek , a tributary to the Arroyo Seco, should be added to surface water flow entering the Cone area. When quantified, this additional flow could have the effect of increasing recharge rate, and therefore, support the need to revise streambed characteristics contained in the model. Since changes in ground water level are partially dependent on the streamflow and stream-aquifer interaction, the accuracy of these characteristics are significant factors.

The purpose of this project was to first develop an estimate of runoff from Reliz Creek and re-evaluate the rate of recharge within the Arroyo Seco channel. Then, if the new information

supported revisions, an update of the hydrologic investigation of the historic benefits would be performed. The project included the following tasks:

Task 1- Data Analysis and Reliz Creek Streamflow Estimation

Task 2- SVIGSM Geologic Verification

Task 3- SVIGSM Refinements

Task 4- HBA Hydrologic Analysis

Tasks 5 and 6- Documentation and project coordination

This Technical Memorandum is organized in the order of the Tasks.

Section 1- Reliz Creek Runoff Estimation

Reliz Creek is a tributary to the Arroyo Seco. The Creek has intermittent flows, mostly in wet years, with a small baseflow component during the spring months. In order to estimate the Arroyo Seco recharge rate to the ground water system an estimation of the daily flows of Reliz Creek, a major component in the stream balance of the Arroyo Seco, was performed. This flow was estimated where Reliz Creek enters the Arroyo Seco Cone near the Elm Street crossing. The confluence of the Arroyo Seco and Reliz Creek is approximately 3 miles downstream of the Elm Street Crossing. Reliz Creek enters the Arroyo Seco Cone at the Elm Street Crossing, but then meanders approximately parallel to the Arroyo Seco until converging near the Thorne Road crossing. Since there are no gaging stations in the Reliz Creek watershed, a rainfall runoff numerical model was developed to simulate the daily runoff generated in the watershed.

A one-day field trip was conducted on June 1, 1999, to observe and note the Reliz Creek watershed physical characteristics and flow regime. The team consisted of Mr. Howard Franklin and Mr. Dennis Lebow of MCWRA and Dr. Ali Taghavi, Consultant to the Agency. Following notes were made on the field trip:

- The upper watershed, generally appears to be steep with granite outcrops rising nearly vertical to the watershed boundary. The middle and lower reaches of the watershed are characterized by a slightly wider channel and overbank area with steep slopes near the watershed boundaries. Throughout the watershed are geologic outcrops of granite and shale, which suggest very little subsurface storage capacity.
- High flashy winter rainfall is common. Although, there are no rain gaging stations in the watershed, the Arroyo Seco near Greenfield precipitation gage (upper bridge on the Arroyo Seco) is a good representation of the rainfall patterns in the Reliz Creek watershed.
- The shallow soil zone does not lend itself to significant underflows in the watershed. The subsurface storage capacity in the watershed is, thus, very limited. This hydrologic characteristic is represented in the vegetation cover of the watershed. Tree density is

sparse throughout, with generally shallow rooted shrubs and phreatophytic vegetation along the creek channel.

- The length of Reliz Creek was either driven by or walked. The surface flow on the day of the field trip was estimated to be approximately 5-10 CFS at the higher reaches, and approximately 1-2 CFS at the middle to lower reaches of the watershed. Flow disappears in some reaches, becoming subsurface base flow. There was no surface flow at the Elm Street crossing on the day of field trip.
- Flow duration and channel depths were estimated through conversations with local residents and high-flow marks on trees and banks.

Reliz Creek Physical Characteristics

Reliz Creek watershed is located in the southwest of the Arroyo Seco Cone area. The watershed area is approximately 24 square miles. Average land elevation in the watershed is 1,390 feet (MSL), and ranges from 420 feet to 4,720 feet. Average annual rainfall in the watershed is estimated to be approximately 22.5 inches with a range of 14 to 35 inches per year. Figure 1 shows the location of Reliz Creek Watershed.

The watershed land use is primarily native vegetation, with some development as ranches for raising cattle. Observations taken during the June field trip indicate that the land cover is approximately 60 percent native vegetation and grassland, and 40 percent trees and other vegetation.

Some of the physical characteristics of the watershed and Reliz Creek are quantified in Tables 1 and 2.

Table 2
Reliz Creek Watershed Hydrologic Soil Type Distribution

Hydrologic Soil Group	Area (acres)	Description
A	27	High infiltration rates. Soils are deep, well drained to excessively drained sands and gravels.
B	1,058	Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.
C	6,633	Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.
D	7,438	Very slow infiltration rates. Soils are clayey, have a high water table, or are shallow to an impervious layer.

Rainfall-Runoff Model Development

A FORTRAN model was developed to simulate the daily runoff from rainfall in Reliz Creek watershed. This model was based on the small watershed routine in the Salinas Valley Integrated Groundwater and Surface Water Model (SVIGSM), and was used independent of the SVIGSM. The model estimates direct surface runoff and ground water subsurface flow for specified watershed characteristics. The method used to simulate direct runoff is similar to the soil moisture accounting component of the SVIGSM. This method is discussed in the SVIGSM Users' Manual (Montgomery Watson, 1995). In general, the rainfall runoff is simulated based on:

- Effective rainfall;
- Hydrologic soil types;
- Predominant land use in the watershed;
- Field capacity, total porosity, and root zone depth of predominant vegetation coverage; and
- Initial soil moisture conditions.

For more details and explanation of the governing equations, the reader is referred to the SVIGSM Users' Manual.

The simulated deep percolation is accumulated as ground water storage. The outflow from the ground water storage is in two parts, a subsurface component and an interflow component, which contributes to the surface runoff from the watershed. The subsurface component is represented as:

$$Q_{wg} = K_{wg} \cdot S \quad (1a)$$

The interflow component is represented as:

$$Q_{ws} = K_{ws} \cdot (S - S_{min}) \quad (1b)$$

Where

Q_{wg}	=	subsurface component of watershed outflow, (L^3/T);
Q_{ws}	=	surface component of watershed outflow, (L^3/T);
K_{wg}	=	subsurface flow recession coefficient;
K_{ws}	=	surface runoff recession coefficient;
S	=	groundwater storage volume underlying the watershed (L^3);
S_{min}	=	minimum threshold groundwater storage, (L^3).

Determination of separate estimates for surface and subsurface contributions are important because the SVIGSM surface flows generally discharge from the watershed in the same time step (1 day). The subsurface flows, on the other hand, generally go to storage and the subsurface discharge from the watershed would be subject to storage effects and the corresponding time lags, which may sometime be more than one time step.

Appropriate physical and hydrologic data was incorporated into the Reliz Creek watershed model. The model output is a daily estimate of the surface and subsurface runoff during the period of simulation. The simulation period is October 1994 to September 1998.

There are no gaging stations in the Reliz watershed that can be used for model calibration. Therefore, field observations and interviews with local residents were used to document estimated flows with corresponding high-flow marks observed in the channel. These flows were used as a means of verifying the range of model simulation results. In addition, the MCWRA has conducted a field study to estimate the high flow during the 1998 runoff season. This study, to which MCWRA associated a potential 20 percent error, estimated an instantaneous peak flow of 1,842 CFS and a mean daily discharge of 1,100 CFS for February 3, 1998. This runoff is generated as a result of a storm that started on January 28, 1998 and lasted through February 3, 1998, with approximately 2.70 inches of rain falling over the Reliz Creek watershed on February 2, 1998. The instantaneous peak flow on the Arroyo Seco and in most coastal streams occurred during the early morning of February 3, 1998. It is assumed that the peak flow on Reliz Creek occurred on February 3rd also, even though the highest daily rainfall occurred before mid-night on February 2, 1998. Because the Reliz model responds to precipitation on a daily time step, the runoff model shows the highest Reliz flows on February 2, 1998. It is apparent that the daily time step used in the model results in some potential, although insignificant, error in the simulation results. A smaller time step, such as hourly or 15-minute would have more closely tracked the storm. However, the objective of the study to evaluate long-term changes in ground water levels in the area, does not support the use of a smaller time step. Appendix A provides documentation of the MCWRA study.

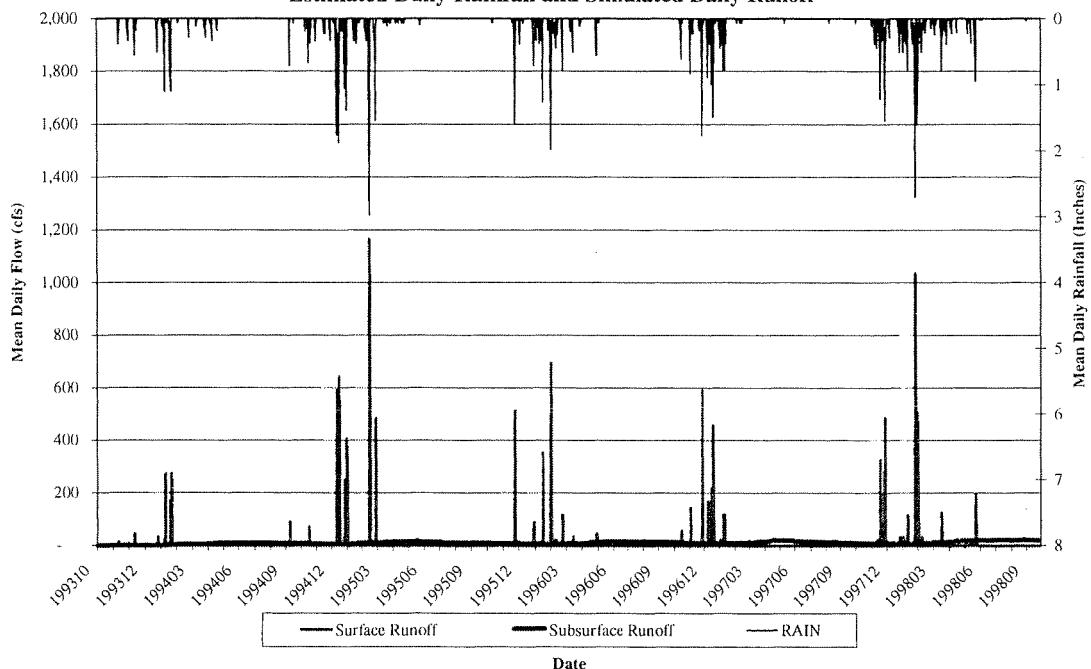

The model parameters were adjusted to obtain a reasonable simulation of the low and high flows. Based on this effort, the model simulated a mean daily flow of 1,035 CFS as a result of the February 2, 1998 rainfall. This estimate is compatible to the 1,100 CFS mean daily flow estimate that is reported by the MCWRA.

Estimation of Daily Runoff

The Reliz watershed model was used to simulate the daily runoff from the watershed during the period October 1994 to September 1998. The average daily runoff during the period of simulation was estimated to be 9 CFS with a maximum daily discharge of 1,166 CFS on March 10, 1995. Figure 2 shows the hydrograph of simulated Reliz Creek watershed daily runoff along with estimated average daily rainfall in the Reliz watershed.

As noted earlier, the Reliz watershed runoff model is a computer program that simulates the daily runoff from rainfall in the Reliz Creek watershed. This model was based on the small watershed routine in the Salinas Valley Integrated Groundwater and Surface Water Model (SVIGSM), and was used independent of the SVIGSM. Reliz Creek watershed model code, input and output data sets are presented in Appendix B.

Estimated Daily Rainfall and Simulated Daily Runoff

Section 2- Arroyo Seco Recharge Rate Estimation

In order to estimate the recharge rate from the Arroyo Seco a water balance approach was used. This approach, similar to that used by the Salinas Valley Coalition (SVC) technical representatives, uses the daily streamflow at upstream (Arroyo Seco near Soledad) and downstream (Arroyo Seco at the Lower Bridge) gaging stations, and estimates the Arroyo Seco recharge rate based on the difference between the daily gage records. The original approach used by the SVC did not account for the contributions from Reliz Creek. The current approach uses the surface runoff contributions from Reliz Creek watershed to properly account for all major water balance components in this reach of the Arroyo Seco.

The water balance equation used is:

$$\text{Recharge Rate} = Q_{US} - Q_{DS} + Q_{RL} - Q_{div} + Q_{Ret}$$

Where:

Q_{US} = Daily upstream flows at Arroyo Seco near Soledad gage, in CFS.

Q_{DS} = Daily downstream flows at Arroyo Seco at Lower Bridge gage, in cfs;

Q_{RL} = Daily estimate of Reliz Creek runoff, in cfs;

Q_{div} = Daily estimate of surface water diversions by Clark Colony; in cfs;

Q_{Ret} = Daily estimate of return flows to the Arroyo Seco from Clark Colony diversion, in CFS.

Sources of data for the water balance equation are as follows:

Q_{US} : Flow records from gaging station;

Q_{DS} : Flow records from gaging station;

Q_{RL} : Simulated flows from the Reliz Creek watershed model;

Q_{div} : Monthly diversion records obtained from the Salinas Valley Coalition; and

Q_{Ret} : Daily estimate of return flows to the Arroyo Seco from Clark colony diversion (Due to the specific types of irrigation and water practices in the area, it is assumed that surface return flows and tail water from the fields back to Arroyo Seco is small enough to be negligible).

The technical representatives of the SVC programmed a simpler version of this formula in a Microsoft® Excel spreadsheet (RECHARGE.XLS) (Hydrologic Consultants, Inc, 1998). This spreadsheet was updated to use additional hydrologic record, as well as the contributions from Reliz Creek watershed. In addition, updates and corrections were made to some of the existing data in the spreadsheet, as follows:

- Updated the provisional data for the Arroyo Seco streamflows at Soledad.

- Adjusted the Clark Colony diversion data (originally supplied by the SVC) to ensure that the estimated daily diversion rates do not exceed available streamflows as recorded by the Arroyo Seco at Soledad gaging station.

Appendix C shows a printout of the Excel Spreadsheet main data sheet.

Based on the revised method, as explained above, the daily average recharge rate from Arroyo Seco to the ground water basin is estimated as 100 CFS, with minimum of 0.5 CFS and maximum of 2,609 CFS. This wide range of recharge rate is due to:

1. Range of flows at the Arroyo Seco near Soledad gage;
2. Range of contributions from Reliz Creek watershed;
3. Recharge rate in the overbank conditions during high flows as opposed to recharge rate within the channel bed.

The table presented in Appendix C shows that during the 1994-1998 period, the Arroyo Seco mean daily flows near Soledad (Arroyo Seco nr Soledad) range from zero to approximately 16,000 CFS. During the same period, the corresponding flows at the Lower Bridge gage (Arroyo Seco Bl Reliz C nr Soledad) range from zero to approximately 17,000 cfs. There have been other high flows estimated and recorded in the recent time scale. These are individual estimated events that are documented in the report "Hydrogeologic Investigation of Arroyo Seco Cone" prepared for MCWRA in April 1994 by Staal, Gardner, and Dunne, Inc. The range of the high flows included in the Staal, Gardner, and Dunne report are within the range recorded in the current investigation. Appendix F of the Staal, Gardner, and Dunne report is reprinted in this report as Appendix D

In a long-term water supply planning study, the average recharge rate would have ordinarily been used. However, to estimate the maximum recharge rate that can conceivably occur within the Arroyo Seco channel, while having statistical significance, the flow with an exceedance probability of one percent is used. Figure 3 shows the flow frequency curve for Arroyo Seco streamflows near Soledad. Based on this flow-frequency curve, the one percent exceedance daily flow is estimated as 3,100 cfs. In other words, during the hydrologic period of October 1994 to September 1998, there is one percent chance that the daily mean flows would equal or exceed 3,100 CFS. Figure 4 shows the relationship between the observed streamflows for the Arroyo Seco near Soledad and the estimated Arroyo Seco recharge rate as calculated based on the foregoing discussion. A 2nd degree polynomial curve is fit to this relationship. Based on the best fit curve, the Arroyo Seco recharge rate corresponding to the estimated daily flow rate of 3,100 CFS is approximately 330 CFS. Although, this recharge rate is based on daily flows during the October 1994 to September 1998 period, it is assumed that this rate would approximate the long-term maximum recharge rate from the Arroyo Seco. It is noteworthy that this four year period contains some of the highest flows encountered on the Arroyo Seco and contains the only gaged flow at the lower station (Arroyo Seco at the Lower Bridge).

Recharge Rate and Hydraulic Conductivity Results

A stage-discharge-wetted perimeter relationship (the same as that used by the SV Coalition) was assumed to estimate the width of the channel and corresponding streambed hydraulic conductivity, K_b . This wetted perimeter relationship is also compatible to that used in the SVIGSM for the Arroyo Seco. Figure 5 shows the relationship between recharge rate and the resulting streambed hydraulic conductivity, K_b . Based on Figure 5, the maximum recharge rate of 330 CFS is attainable by having a streambed hydraulic conductivity in the range of 4-6 feet per day. The 4-6 feet per day hydraulic conductivity has therefore been used in the SVIGSM for this update on the Arroyo Seco Cone. The SVIGSM dynamically calculates the river stage based on the streamflow rates. At each time step, the river stage is used in conjunction with the groundwater levels at the corresponding location to develop a hydraulic gradient. The model, then uses this hydraulic gradient along with the streambed hydraulic conductivity to calculate the recharge rate for the specific location and time step. For more detailed explanation on the SVIGSM simulation of stream-aquifer interaction, refer to the SVIGSM Users' Manual

Section 3- Historical Benefits Analysis (HBA)

The SVIGSM was used to determine the hydrologic impacts of the Historical Benefits Analysis from the operations of the Nacimiento and San Antonio reservoirs. The estimates of the recharge rate and corresponding streambed hydraulic conductivity for the Arroyo Seco were revised to reflect the new estimates of the Arroyo Seco recharge rates, as estimated by the water balance process explained in Section 2 of this Technical Memorandum. With significant revisions to a major recharge source such as the Arroyo Seco, the hydrologic investigation of the HBA also requires updating. This update is limited to the estimate of the long-term average annual changes in ground water levels. No analysis of the impacts to the water supply wells, flood control, and economic benefits are considered.

Before revision of the hydrologic impacts, a verification of the geologic conditions in the Arroyo Seco, as well as recalibration of the SVIGSM were performed.

SVIGSM Conceptual Geology in Arroyo Seco Cone Area

The SVIGSM geologic stratification is based on a number of geologic reports and investigations that have been conducted up through the development of the model in 1995. Task 2 of the scope of work of this project requires a comparison of the geologic stratification of the SVIGSM in the Arroyo Seco area with the geologic cross-sections presented in the Arroyo Seco hydrogeologic Investigation, prepared for the MCWRA in April 1994, by Staal, Gardner, and Dunne, Inc.

To perform such an analysis, two representative cross-sections, a north-south and a west-east, are selected from the report. The cross-sections most compatible in location to those in the SVIGSM are 5-5' and D5-D5'. The locations of these cross-sections are shown in Figure 6, and the cross-section profiles are shown in Figures 7A and 7B. A comparative set of cross-sections is produced from the geologic database in the SVIGSM. These are called S5-S5'(approximately corresponding to 5-5') and SD5-SD5' (approximately corresponding to D5-D5'), and are shown in Figures 8A and 8B.

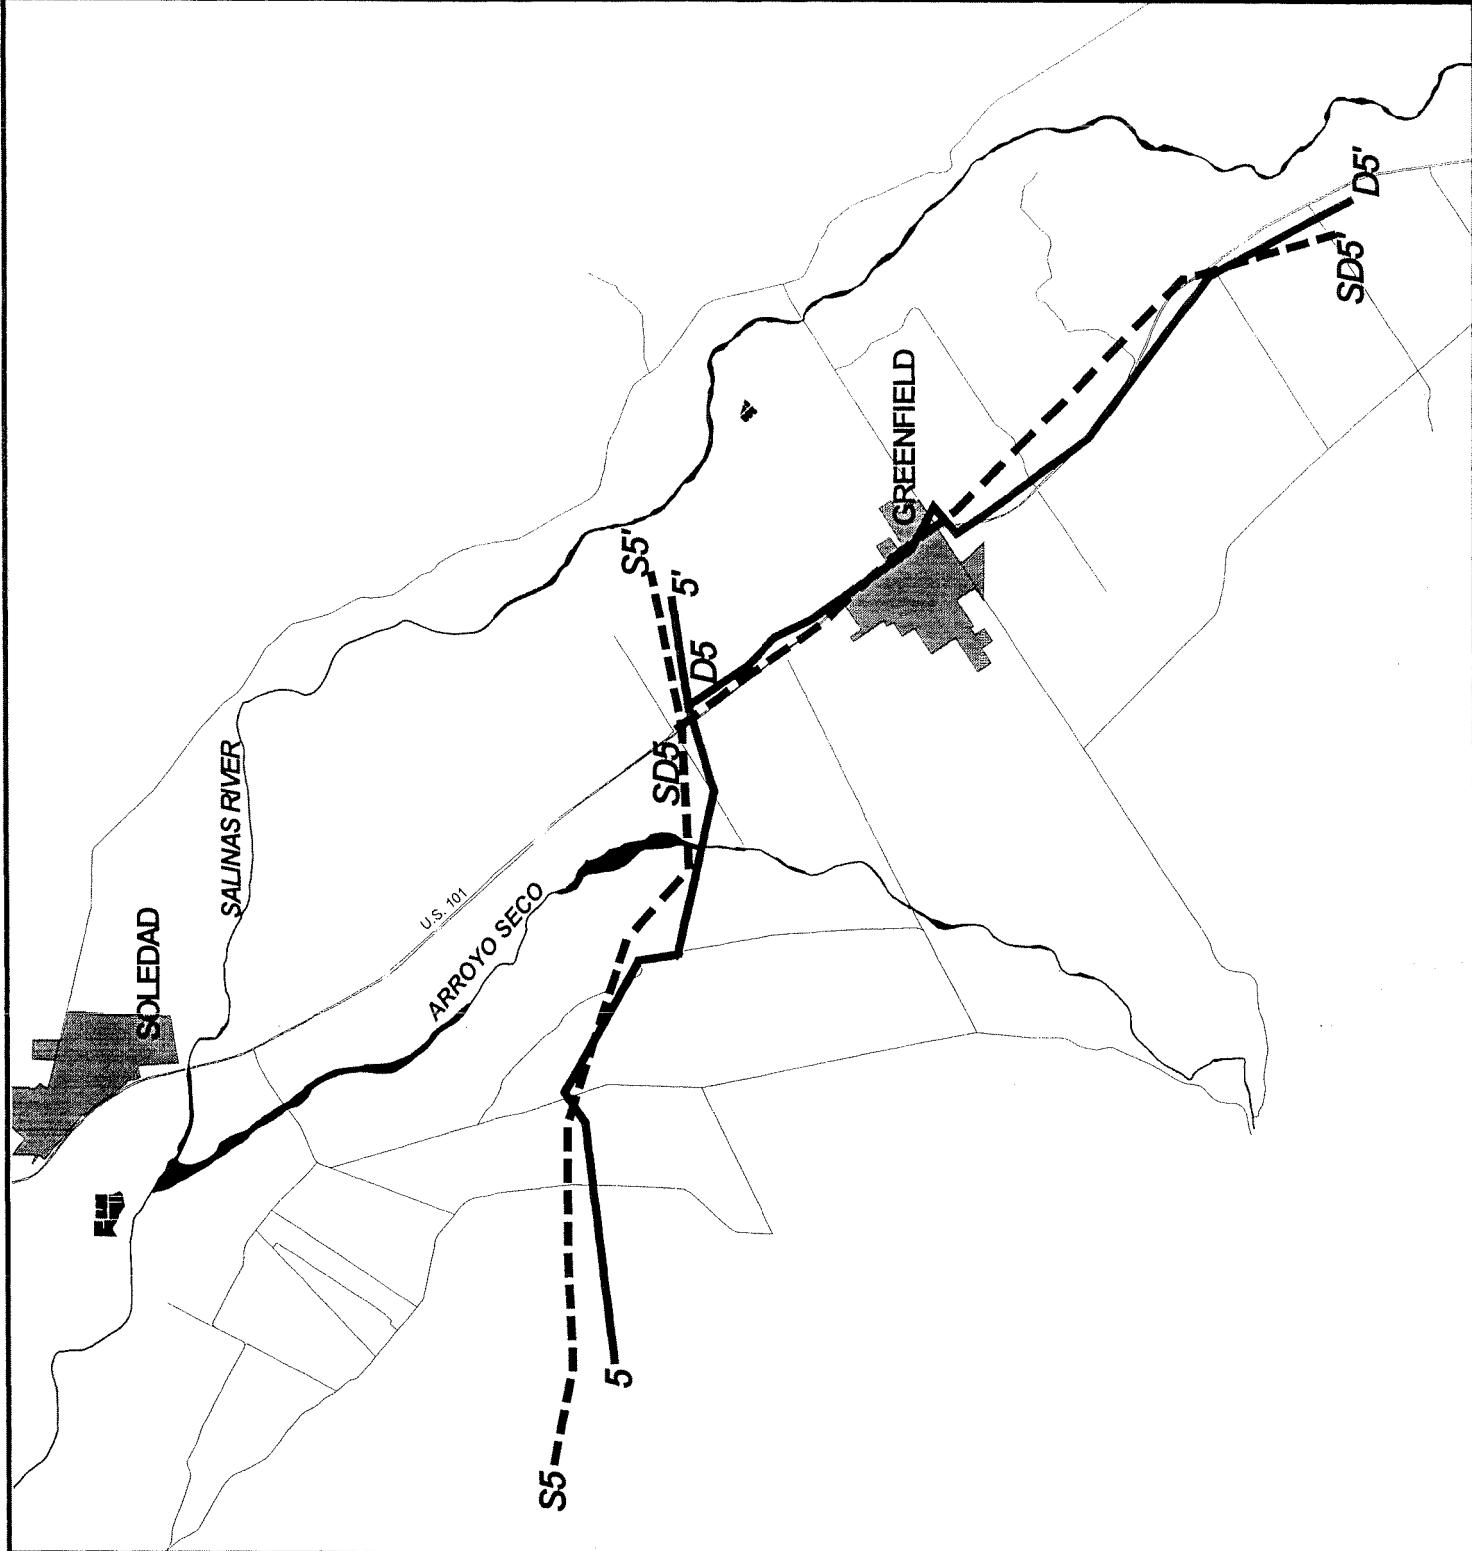

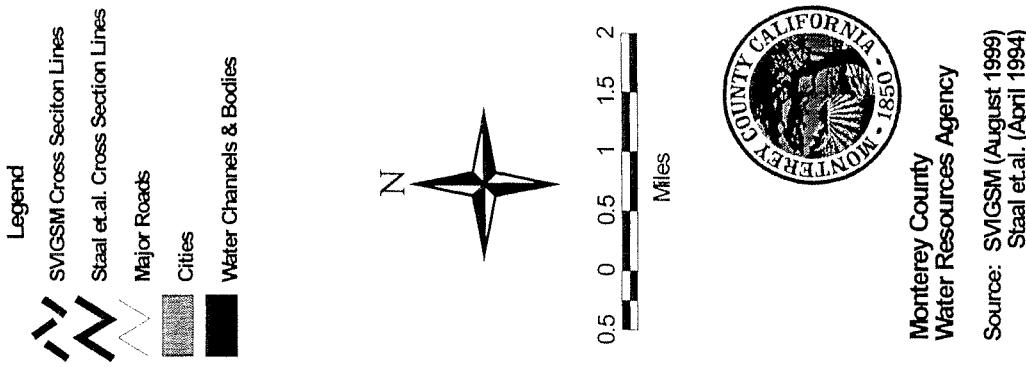

A comparison of the sets of north-south cross-sections indicates that an alluvial gravel formation exists from ground surface to approximately a depth of 250-300 feet below surface. The cross-section shows that a thick clay deposit of approximately 100-150 feet underlies the gravel deposits. However, the sand and sandy clay indicators in the well logs show that the clay is not as thick, and may have a thickness of about 50 feet. The D5-D5' cross-section does not go deep enough to present the second aquifer layer. In comparison, the SD5-SD5' SVIGSM cross-section shows the layer 1 aquifer with a thickness of approximately 200-250 feet and is underlain by an aquitard of approximately 20-50 feet thick.

The west-east cross-section 5-5' shows a thick gravel deposit approximately 300 feet at the surface. The thickness of this water-bearing deposit does not change significantly from Arroyo Seco Road to the Arroyo Seco. The deposit thins out to about 220 feet thick towards Salinas River. Clay and sandy-clay material with thickness of approximately 80-250 feet underlie the

water-bearing deposit throughout the cross-section. A second layer of gravel deposit is present starting at depth of 400 feet below ground surface. In comparison, the S5-S5' cross-section in SVIGSM shows the aquifer layer 1 with thickness of 250-300 feet in the west, and thinning out to a thickness of 150-200 feet as it crosses the Salinas River. Although the clay deposit in SVIGSM, representing the aquitard underlying the layer 1, is not as thick as shown in cross-section 5-5', the aquifer layer 2 has approximately same thickness as that in cross-section 5-5' (50-200 feet). The cross-section 5-5' is not deep enough to show the third aquifer layer.

The data and information available from the 1994 Arroyo Seco Hydrogeologic Investigation indicates that the geologic stratification of the SVIGSM is reasonably representing the conceptual geology of the Arroyo Seco Cone area. In general, the thickness of the aquifer material in the SVIGSM is similar to those represented in the well log cross-sections. The aquitards may not be represented as thick as those shown in the well log cross-sections. However, the effect of this difference on subsurface flow is accounted for by adjusting the aquitard vertical permeability parameters in the model.

SVIGSM Re-calibration

As part of the HBA study, the SVIGSM was calibrated for the hydrologic period 1949 to 1994. The revised estimates of the streambed hydraulic conductivity of the Arroyo Seco were incorporated in the model. The streambed hydraulic conductivities (4-6 feet per day) was assigned to the stream nodes in descending order based on the streambed depositional environment. The model dynamically simulates the stream-aquifer interaction and corresponding recharge rates for the Arroyo Seco based on formulas that use the hydraulic conductivity and hydraulic gradient between stream stage and ground water levels on a daily basis. Due to changes in the Arroyo Seco recharge rate between the previous HBA efforts (April 1998) and this project, the SVIGSM aquifer hydraulic parameters were also modified in the Arroyo Seco Cone area to obtain a reasonable calibration result. The revised hydraulic parameters are presented in Table 3.

The model simulation results were compared against hydrograph of observed ground water level at the calibration wells. Appendix E shows the hydrograph for calibration wells 65 – 73 located in the Arroyo Seco Cone area.

In addition, to gain confidence in the model simulation results of the stream-aquifer interaction, a scatterplot of Salinas River simulated and observed gains are presented in Appendix E. These scatterplots are very similar to those presented in the April 1998 HBA report, and verify that the model calibration results are reasonable.

An analysis of model simulation results indicated that no significant changes were observed in the model calibration in other areas of the Valley. However, the changes in the Arroyo Seco recharge rate and model calibration have some impacts on the hydrologic benefits received in the Arroyo Seco Cone area that will be discussed in the next section

Table 3
Range of Original and Revised Aquifer Hydraulic Parameters Used in the SVIGSM for the
Arroyo Seco Cone Area

Parameter	Layer	April 1998 HBA			Present Study		
		Average	Minimum	Maximum	Average	Minimum	Maximum
Hydraulic Conductivity (Ft/Day)	1	200	90	280	80	40	100

Estimation of Hydrologic Benefits

After recalibration of the model, the SVIGSM was used to perform the HBA analysis for the model simulations of the ground water conditions “with” and “without” reservoir operations during the historical period 1958-94. Table 4 shows the summary of the average annual changes in ground water levels in each Economic Study Unit (ESU). The values shown in Table 4 represent weighted average annual ground water levels. The weights used for averaging are both temporal (based on monthly irrigation patterns) and spatial (based on relative ground water pumping that occurs at each node). Given the non-uniform geographic distribution of ground water pumping in the Salinas Valley, this method of averaging represents a more realistic subarea-wide average. Based on this table, the average annual hydrologic benefits in the Arroyo Seco Cone area (ESU 8A) is approximately 5.5 Feet. This table also indicates that there are some minor changes in the level of benefits in the other ESUs outside the Arroyo Seco cone. These values ranged from -0.5 feet to 0.6 feet. However, no significant changes are observed in the ESUs upstream from the Arroyo Seco confluence with the Salinas River. Table 5 shows a comparison of the estimates of hydrologic benefits made in April 1998 and those based on this update and revised study. Note that the level of hydrologic benefits in the Arroyo Seco Cone area is approximately 0.4 feet less, with very small changes in other areas of the Valley.

Figures 9 and 10 present the average annual valley-wide water balance in the ground water aquifer during the 1958-94 hydrologic period, for the historical simulation scenario and that for the conditions with no upstream regulation (no reservoir case). These Figures indicate that the average annual deep percolation is approximately 219 TAF/Yr and the average annual recharge from streams is approximately 257 TAF/Yr (respectively, 2 TAF/Yr less and 2 TAF/Yr more than the April 1998 estimate). The historical rate of change in fresh ground water storage is estimated at -22 TAF/Yr (compared to -19 TAF/Yr in the April 1998 estimate) during the period of 1958-94, while the average annual rate of seawater intrusion is estimated at 11 TAF/Yr (similar to the April 1998 estimate). Under the no-reservoir conditions, the average annual change in fresh ground water storage is estimated at -43 TAF/Yr (compared to -45 TAF/Yr in the April 1998 estimate).

Figures 11 and 12 show similar water balance diagrams for each model subarea. A comparison of these figures and those presented in the April 1998 HBA report shows that the historical stream recharge in the Upper Valley and the Forebay area have been impacted by the refinements in the model. The average annual stream recharge in the Upper Valley is simulated to be 91 TAF/Yr (approximately 1 TAF/Yr less than the April 1998 report), while that in the Forebay area is 98 TAF/Yr (approximately 3 TAF/Yr more than the April 1998 report). The changes in the stream recharge under the no-reservoir conditions are also in the same order of magnitude as the historical.

In general, while the April 1998 report estimated that the rate of change in fresh ground water storage in the Forebay area was improved by 5 TAF/Yr as a result of the operation of reservoirs, the current study results in an 6 TAF/Yr improvement in the rate of change in the fresh ground water storage in the Forebay area.

Figure 13 shows the geographic distribution of the benefits throughout the Valley, based on the revised and updated study.

Section 4- Scope and Limitations of SVIGSM Application

The IGSM is a comprehensive hydrologic model that simulates the various components of the hydrologic cycle and their interaction.

The IGSM is generally used for water supply planning purposes to investigate various water demands and supply options in a complex river basin. Compared to other similar models, the IGSM is considered a state-of-the-art model, in both theory and application. The IGSM has been in the forefront of numerical tools to assist in planning and management of river basins in California. The IGSM has been used for analysis of surface water and ground water supply and conjunctive use planning in basins ranging from 50 to 20,000 square miles.

The Salinas Valley application of the IGSM, the SVIGSM, was developed in 1993 for purposes of basin planning and management in Salinas Valley. The model was originally developed as an integrated hydrologic model of the Valley and calibrated for the period 1970-90. Subsequently, a reservoir operation module was added to the code and the hydrologic database was extended to include 1949 to 94. The SVIGSM has been applied to the following projects:

1. Salinas Valley Basin Management Plan (BMP), Water Supply Analysis;
2. Castroville Seawater Intrusion Project;
3. Salinas Valley BMP Alternatives Analysis;
4. Salinas Valley BMP Facilities Requirements and Sizing;
5. Analysis of Operation of Nacimiento and San Antonio Reservoirs;
6. Analysis of Re-operation of the Reservoirs;
7. Hydrologic Investigation of Historical Benefits Analysis (HBA);
8. Analysis of Agricultural Pumping Estimation in the Valley;
9. Analysis of Ground Water Monitoring Program in the Valley; and
10. Salinas Valley Water Project (SVWP), EIR.

In simple terms, the goal of SVIGSM, and generally any numerical model, is to simulate the complex hydrologic processes and their inter-relationship through the solution of a series of mathematical formulas. The degree and accuracy that these mathematical formulae represent the complex hydrologic processes depend on a number of factors, including:

- Nature and complexity of the hydrologic process,
- Accuracy of observations and records that are utilized to develop the model theory,
- Range of parameters selected, and
- Accuracy of calibration of the formula to the observed record.

For example, the accuracy of a simple regression model depends on (i) goodness of fit (R^2) to the data, (ii) order of regression equation (e.g., linear or second degree), (iii) range that the equation is valid for, and (iv) accuracy and reasonableness of the parameters.

In the case of a complex hydrologic model, generally, multi-degree and multi-order differential equations are used to represent the hydrologic process. In simple terms, these equations are combined to represent the inter-relationship of the processes.

The accuracy of the SVIGSM depends on the accuracy of calibration and host of data and parameters used in the model. These include, but are not limited to the following:

- Accuracy of the streamflow and ground water level observed records;
- Accuracy and consistency in other climatological and hydrologic data, such as evaporation and evapotranspiration, and rainfall data;
- Estimates of land use and crop mix acreage;
- Estimates of ground water pumping and distribution;
- Consistency between the land use and crop mix data and water use estimates;
- Estimates of geologic stratification and hydrogeologic parameters;
- Estimates of boundary conditions used in the model; and
- Accuracy and consistency in the reservoir operation data.

The daily surface water simulation capabilities of the SVIGSM have been calibrated to a set of observed daily streamflow data from various gaging stations in the Valley. The ground water simulation capabilities are calibrated against a set of observed ground water level data from a number of wells selected throughout the Valley. The results of the latest calibration, prior to the minor re-calibration performed in this project, are published in Appendix A of the April 1998 HBA final report.

Based on the calibration results, the model has been approved by the technical advisors and representatives of Salinas Valley stakeholders who participated in the IGSM Technical Workshops held during 1997 and 1998. Participants determined the model was suitable for use as a regional planning numerical tool to assess the regional impacts of the historical operations of the reservoirs on the downstream surface water and ground water conditions. During the Workshops, it was also agreed that the SVIGSM would be suitable for selecting the best alternative project for halting seawater intrusion, balancing the basin and meeting future water demand.

Although, the model simulates the ground water flow conditions at each of the finite elements, the scale of some of the input data, such as land use and ground water pumping is at the regional or subarea level. This limits the accuracy of the model simulations when used in geographic areas that are substantially smaller than the hydrologic subarea. In general, the model accuracy diminishes as the geographic boundary of the analysis area gets smaller.

In order to evaluate these impacts in more detail geographic areas than the model subareas, the major hydrologic subareas of Pressure, East Side, Forebay and Upper Valley were further broken down into smaller sub-units, called Economic Study Units (ESU). Although these sub-units were called ESUs, a major factor in delineation of the extent of ESU boundaries was the range and distribution of the hydrologic benefits as estimated from changes in average annual ground water levels. Subsequently, in order to determine landmarks for the boundaries of ESUs, the boundaries were adjusted from the SVIGSM finite elements to physical features on land, such as roads, ditches, and creeks.

Therefore, in order to prevent violation of the accuracy of the model, it was suggested and agreed upon in the SVIGSM Workshops, that the level of accuracy of HBA analysis would be limited to the summary tables presented for each ESU.

The accuracy in the contour maps prepared to represent the impact of reservoir operations on changes in ground water level also is dependent on the accuracy of the model results. Since there are inherent errors built into both the model simulations and observed records, the accuracy of the model has generally been reported as ± 5 feet throughout the Valley. The scale of this accuracy is different in various subareas. Figures 14a through 14d show a statistical breakdown of the residual ground water levels by subarea and by aquifer layer. The distributions of residual ground water levels show the percentage of residuals within the specified ranges. A higher percentage of residuals near zero, and a more centered the distribution around zero, indicates a better simulation of historical conditions.

Based on these statistical breakdowns, model performance in each subarea can be summarized as follows:

Pressure Subarea- The majority of the simulated ground water levels lie within ± 10 feet of observed values. Approximately 56 percent of the residuals lie within ± 5 feet, and 78 percent of the residuals lie within ± 10 feet. In general, the distributions for the 180-foot Aquifer, the 400-foot Aquifer, and the total Pressure Subarea appear bell-shaped and centered around the zero point. The distribution for the Deep Aquifer shows somewhat more spread. This distribution may be skewed by the limited number of wells and the limited number of data points for each well in the Deep Aquifer. Pumping and data collection from the Deep Aquifer began in the mid-1980s.

East Side Subarea- Distributions of the residuals in the East Side Subarea show that 33 percent of the simulated ground water levels lie within ± 5 feet of observed levels, and 54 percent lie within ± 10 feet. For similar reasons described in the SVIGSM Update Report, these distributions show more spread than in other subareas. In general, the model was calibrated to reasonable agreement with regional trends in ground water levels and as many of the calibration wells as possible. The distributions tend to be centered around the zero point, with the exception of the East Side Shallow Aquifer, which may be skewed by the relatively small number of calibration wells.

Forebay Subarea- The distribution of residuals, as well as the calibration hydrographs, show good calibration between simulated and observed ground water levels. Overall, 60 percent of

the residuals are in the ± 5 feet range, and 84 percent are in the ± 10 feet range. The distributions appear to be normal-shaped and are centered slightly (less than 5 feet) higher than the zero point.

Upper Valley Subarea. Simulated ground water levels tend to match observed values fairly well in the Upper Valley. As the residual distribution shows, the majority of the residuals are in the ± 5 feet range. Specifically, 80 percent of the residuals are within the ± 5 feet range, and 91 percent are within the ± 10 feet range. The distribution is normal-shaped and is centered around the zero point.

Although the statistical accuracy of the model is different in each subarea, based on the error histograms presented, a valley-wide level of accuracy of ± 5 feet is generally acceptable. The final HBA ground water impact contours are thus presented with a 5-feet interval to honor the accuracy of the analysis. Study of the historical benefits at a more detail level may violate the accuracy of the analysis.

Section 5- Summary

The purpose of this project was to re-evaluate the recharge rate from the Arroyo Seco channel, and update the hydrologic investigation of the Historical Benefits Analysis (HBA) for the Arroyo Seco Cone area. The project included the development of a rainfall runoff model for the Reliz Creek watershed to estimate the runoff contributions from the Reliz Creek to the Arroyo Seco. This runoff contribution affects the estimate of the rate of Arroyo Seco recharge to the ground water basin. Based on a mass balance approach, it is concluded that the Arroyo Seco maximum recharge rate is 330 CFS per day under stable, equilibrium conditions. The corresponding hydraulic conductivity of the Arroyo Seco channel bed is approximately 4-6 feet per day.

The SVIGSM parameter data is updated based for the new estimates of the Arroyo Seco streambed parameters. Subsequently, the aquifer hydraulic parameters in the Arroyo Seco Cone area are appropriately adjusted to ensure that the model calibration is valid. The model calibration is verified by evaluating the simulated ground water levels against the observed ground water levels at the model calibration wells in the Arroyo Seco Cone area. Note that the new streambed hydraulic parameters used for the Arroyo Seco represent the extreme conditions, and the aquifer hydraulic parameters in the Cone area are adjusted to calibrate the model to such high recharge conditions. While the aquifer hydraulic parameters in the Cone area represent local hydrogeologic conditions, the parameters in other areas, including those upstream of the Cone area represent regional hydraulic conditions. This has caused the model calibration results to be somewhat less accurate relative to the previous version of the model calibration. However, the simulation results are still within the acceptable range of model errors, and can be used for the future HBA and other regional analyses.

In addition to the estimation of Reliz watershed daily runoff and estimation of Arroyo Seco recharge rate, to ensure that the model geologic stratification represents the latest published data, a comparison of two model cross-sections is made with two corresponding cross-sections from the Arroyo Seco Cone Hydrogeologic Investigation report prepared for the MCWRA in April 1994. The results show that the model geological stratification represents the regional conditions reasonably well.

The hydrologic investigation of the HBA is revised, based on the changes to the SVIGSM. The revised analysis shows that the long-term average annual hydrologic benefits to the Arroyo Seco Cone area due to the historical operations of the reservoirs, is approximately 5.5 feet of higher ground water levels. This hydrologic benefit is approximately 0.4 feet less than the estimate made in April 1998. Figure 13 shows the distribution of the benefits within the Valley. The hydrologic benefits to other parts of the Valley are not substantially affected by the revisions to the analysis.

Appendix A

MCWRA data collection on Reliz Watershed

This appendix includes the supporting material for the Arroyo Seco permeability investigation, prepared by Mr. Dennis Lebow of MCWRA, and submitted on May 23, 1998 for use in this project.

Date: May 23, 1998

Montgomery Watson
Attn.: Ali Taghavi
777 Campus Commons Rd., Suite 250
Sacramento, Ca. 95825-8308

Subject: Hydrogeologic data for the Arroyo Seco area.

Dear Mr. Taghavi:

Enclosed are supporting materials for the Arroyo Seco permeability investigation:

1. A table displaying peak discharges, mean daily discharges, mean daily vs. peak discharges, and mean discharge per square mile of watershed area for Reliz Creek and three other watersheds.
2. A graph displaying the estimated correlation between the Arroyo Seco mean daily flows and Reliz Creek mean daily flows.
3. Peak discharge estimate on Reliz creek for the storm of February 3, 1998.
4. Pictures displaying the reach of Reliz creek used to estimate peak flow for February 3, 1998.
5. Preliminary USGS discharge data for the Arroyo Seco near Soledad and the Arroyo Seco below Reliz.
6. Manual discharge measurements made on Reliz creek and Arroyo Seco river on 04/22/98 and 05/05/98.
7. For a non-related matter, also enclosed are the 1995 and 1996 ground water extraction data reports.

If you have any questions or need any additional information, please feel free to call me at (408) 755-8912.

Sincerely,

Dave Diller
Hydrographer

11152050 ARROYO SECO BELOW RELIZ CREEK, NEAR SOLEDAD, CA

LOCATION.—Lat 36°23'59", long 121°19'23", in Los Conches Grant, Monterey County, Hydrologic Unit 18060005, on right bank at county road bridge, 1.7 mi south of Soledad, and 7.4 mi downstream from Reliz Creek.

DRAINAGE AREA.—304 mi².

PERIOD OF RECORD.—October 1994 to current year.

GAGE.—Water-stage recorder and crest-stage gage. Datum of gage is 167.93 ft above sea level (levels by Monterey County).

REMARKS.—Records poor. No regulation or large diversion upstream from station. Low flows affected by upstream gravel mining and irrigation during summer months. See schematic diagram of Salinas River Basin.

EXTREMES FOR PERIOD OF RECORD.—Maximum discharge, 31,000 ft³/s, Mar. 10, 1995, gage height, 9.62 ft, rating affected by backwater from Salinas River. Discharge estimated by routing peak. No flow for many days.

EXTREMES FOR CURRENT YEAR.—Peak discharges greater than base discharge of 2,500 ft³/s, or maximum:

Date	Time	Discharge	Gage height	Date	Time	Discharge	Gage height

Appendix C

Arroyo Seco Recharge Estimation

This appendix includes printout of the EXCEL spreadsheet table used in estimation of recharge rates for the Arroyo Seco.

Update of the Historical Benefits Analysis (HBA) Hydrologic Investigation

Analysis of daily recharge in Arroyo Seco

Q1 = measured flow at USGS station 11152000, "Arroyo Seco nr Soledad" (cfs)

Q2 = measured flow at USGS station 11152050, "Arroyo Seco Bl Reliz C nr Soledad" (cfs)

D = diversions by Clark Colony (cfs)

Parameters:

52800	Length of Arroyo Seco channel from Q1 to Q2 (ft)
0.35	Coefficient in width-discharge function
19.9	Constant in the relationship
85	Max width of AS channel (ft)
130	Discharge where max width applies (cfs)
1	Hydraulic Gradient (Hs-Hg)/bs
	Normal Values Used

Day	Q1 (cfs)	Q _{Relize} (cfs)	D (cfs)	Q2 (cfs)	Gain(-ve) / Loss(+ve) (cfs)	+ve Recharge (River Loss Rate) (cfs)	Width (ft)	Bed K (ft/Day)

Appendix D

Hydrologic Data- Monterey County Water Resources Agency Arroyo Seco Observations

This appendix presents the hydrologic data collected for a study conducted in April 1994 by Staal, Gardner, and Dunne, Inc., titled "Hydrogeologic Investigation, Arroyo Seco Cone". The information was originally published in Appendix F as Table F-1 and is reprinted here as Appendix D.

Table D-1. Monterey County Water Resources Agency Arroyo Seco Observations

MCWRA Arroyo Seco Observations					
Date	Time	Description	Q - cfs	Middle	Bridge
12/22/64	920	GH about 2.0, Q about 150, flow thru	150	400	1000
12/23/64	940	GH about 2.0, Q about 175, flow thru	175	1364	630
04/09/65	1045	Q 100, flow thru	100	370	1100
11/23/65	500	no flow visible		261	daily
12/13/65	1000	Did not reach Salinas River		112	daily
02/01/66	1200	flow thru		250	daily
12/05/66	1015	GH 2.8, est. Q 1,000, Thru to Salinas	1000	3000	1000
12/17/66	?	Stopped flowing		158	daily
02/21/67	1400	est. 5 - 7 cfs flowing	7	185	daily

02/21/80	1500	GH 4.25, est. 6-7000 cfs	7000	6184	1435
12/04/80	1115	est. 30 - 40 cfs	40	1005	930
03/30/82	?	MB obser. rec. - flow to Salinas River		499	1037
11/30/82	1130	Flow dropping off - gage height = 3.50		2626	1200
11/30/82	1020	Peak flow, gage height = 3.75'		4874	715
12/01/82	1020	Still good flow through to Salinas, est. 400 cfs	400		
12/22/82	1000	Good flow through lower bridge		2271	1030
11/11/83	?	Through to Salinas (from MB obs.)		1415	415
11/25/85	915	Flow under lower bridge, thru to Salinas ?		644	daily
12/02/85	1200	Flow thru lower bridge, nearing confluence		2124	1215
12/03/85	950	Flow approx. 150' wide, GH 2.1, Q 300	300		
02/13/86	1015	Iots of water - GH = 3.5		2000	daily
10/08/86	1000	Flow thru lower bridge		199	daily
03/04/91	930	Good flow thru to Salinas River, GH 2.2		2200	700
03/06/91	1130	Flow roughly 200'wide at bridge, GH .9		308	1200
03/10/91	1430	GH 1.3, light turbidity		421	1250
03/20/91	1000	Flow covers channel from pier 21 to 10, GH 2.3		1175	1020
02/11/92	1220	Flow thru to Salinas River, bank to bank		2281	1232
01/07/93	930	GH 3.0, Q 3000 approx, river flowing 550	3000	5814	200

Appendix E

SVIGSM Calibration Well Hydrographs in the Arroyo Seco Cone Area

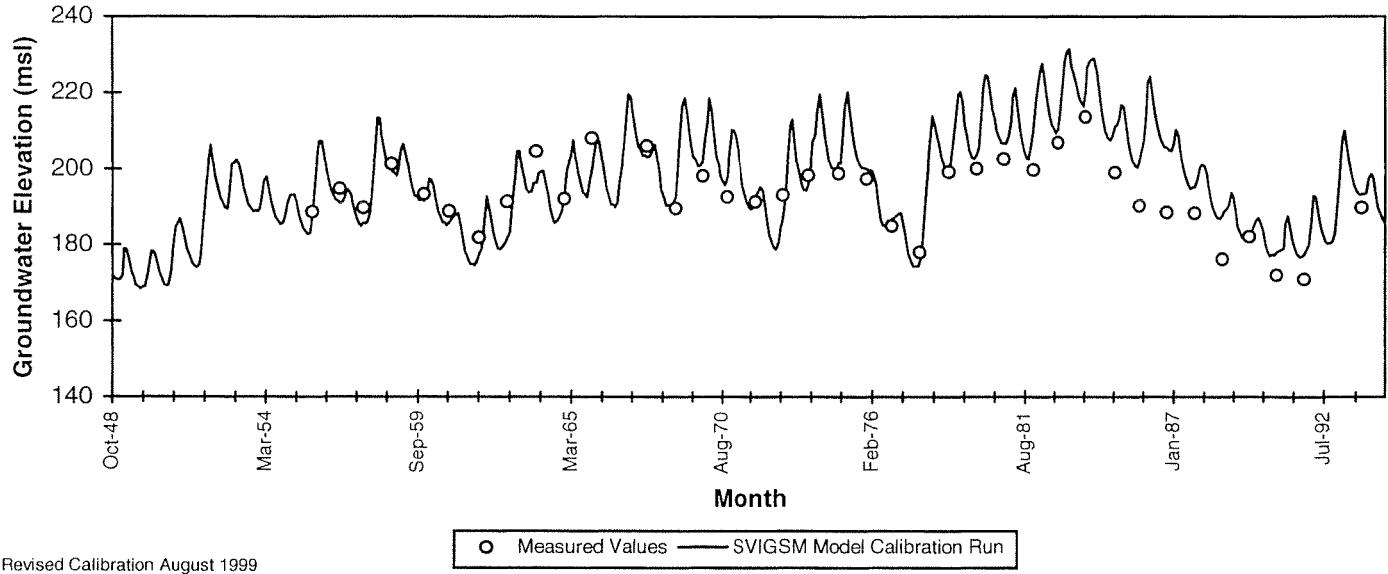

This appendix includes hydrograph of simulated and observed ground water levels for the SVIGSM calibration wells in the Arroyo Seco Cone area. Table E-1 presents the State well ID number, along with the construction information available for each calibration well.

Table E-1. Construction Information for SVIGSM Calibration Wells in the Arroyo Seco Cone Area
